L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

2D interaction of a Gaussian Beam with a dichroic surface for the modeling of quasi-optical systems

K. Elis ^{*†‡}, A. Chabory [†], J. Sokoloff [‡], S. Bolioli [§]

Abstract — One solution to model quasi-optical systems - systems generally constituted by elements of large dimension with respect to the wavelength - is to use asymptotics, such as Gaussian Beams (GB) based techniques [1]. In these systems, dichroic surfaces are used to split, filter or mix an input signal. However, these surfaces are generally made of periodic elements of size that does not exceed a fraction of wavelength. Therefore, they cannot be modeled by such methods. In this paper we propose a technique, based on a spectral representation, to treat the interaction of a GB with a dichroic surface, we suppose that the fields reflected and transmitted by the interface can be approximated by GBs.

1 Introduction

In mm-wave radiometry, quasi-optical systems are used to guide, filter, split or mix the input signals. Such systems are generally constituted by the combination of different elements, e.g. mirrors, lenses, dichroic filters, or horn antennas. The number and the size of these elements render their modeling difficultly amenable by classical methods in acceptable computation times. For such systems, even physical optics may become computationally too costly. Gaussian beams constitute a possible alternative. The interaction of a GB with many of these elements is well-known (because their size is greater than few wavelengths). Indeed, in [2], Deschamps has demonstrated that the fields reflected and/or transmitted at a dielectric/metallic interface illuminated by an incident GB can be approximated by Gaussian beams. However, dichroic surfaces are in some cases structures which period may not exceed a fraction of wavelength. Thus they cannot be modeled by such methods.

One solution to integrate these elements consists in computing its response with the help of the method of moments coupled with Bloch/Floquet modal description. This allows the representation of the dichroic surface by reflexion and transmission coefficients.

In this article, we analyze the interaction between

a GB and a dichroic surface. We suppose that the fields reflected and transmitted by the interface can be approximated by GBs. The characteristics of these two GBs are found by means of a technique based on a spectral representation. Analytical expressions of the fields at any part of space are obtained via the asymptotic steepest descent path method.

This article is divided in five sections. The second section briefly presents GBs. The third section details the context and the configuration. The fourth section explains the principles of our method. The fifth section is dedicated to the results and comparisons with a reference method. In the last section, we conclude and discuss possible future works.

2 Gaussian Beams

2.1 General points

Gaussian beams are solution of the electromagnetic wave equation upon the paraxial approximation, which requires that the field is only weakly diverging with respect to its main propagation direction. The maximal angle of divergence generally admitted is of 20° . This study is in two dimensions with $\hat{\mathbf{y}}_i$ as the direction of invariance. The reference frame of the incident beam is $(0, \hat{\mathbf{x}}_i, \hat{\mathbf{z}}_i)$. In this article, we only present the case in which the electric field is transversal to $\hat{\mathbf{z}}_i$ (TE). Note that the Transversal Magnetic case (TM) can be formulated in a similar way.

2.2 Used GBs

In this article, we use a general formulation of GBs. This formulation is chosen to be as general as possible in order to be able to describe accurately the reflected and transmitted fields. A GB is characterized by a reference frame and four parameters : a complex amplitude a_{i0} , a spatial shift x_{i0} , a phase shift β_i and a complex curvature radius q_{i0} . We can develop q_{i0} as $jk \frac{W_{i0}^2}{2} - z_{W_{i0}}$, with W_{i0} the size of the beam waist, and $z_{W_{i0}}$ the position of this waist along the propagation direction. In the plane $z_i = 0$, the electric field is oriented along $\hat{\mathbf{y}}_i$ and given by

$$u_i(x_i, 0) = a_{i0} e^{j \frac{k}{2q_{i0}} (x_i - x_{i0})^2} e^{-j\beta_i x_i}, \quad (1)$$

[‡]LAPLACE, Université Paul Sabatier, 118 route de Narbonne, 31062 Toulouse, France.

[§]DEMR, ONERA, 2 av. E. Belin, 31055 Toulouse, France

We can deduct its plane-wave spectrum by means of a Fourier transform of (1). This yields

$$\tilde{u}_i(k_{x_i}) = a_{i0} \sqrt{-j \frac{2\pi}{k}} q_{i0} e^{j \frac{(k_{x_i} - \beta_i)^2}{2k} q_{i0}} e^{j k_{x_i} x_{i0}}, \quad (2)$$

with k_{x_i} the wave vector along the x_i axis. This formulation is more general than those usually used. Indeed it includes several other formulations:

- For $z_{W_{i0}} = 0$, this formulation is identical to the Gabor phase-space beams [3] employed in the Gabor-Frame and Gabor-Base expansions.
- For $\beta_i = 0$, this formulation is the same as the fundamental GB. Note that the 2D interaction of this type of GB with a dichroic surface as been studied in [5].

2.3 Paraxial formulation

In TE, if the direction of propagation is along $\hat{\mathbf{z}}_i$, the paraxial vectorial expression is given by

$$\begin{aligned} \mathbf{E}_i(x_i, z_i) &= u_i(x_i, z_i) \hat{\mathbf{y}}_i, \\ \mathbf{H}_i(x_i, z_i) &= -\frac{1}{Z_0} \left(u_i(x_i, z_i) \hat{\mathbf{x}}_i - \frac{j}{k} \frac{\partial u_i(x_i, z_i)}{\partial x_i} \hat{\mathbf{z}}_i \right), \end{aligned} \quad (3)$$

where \mathbf{E}_i and \mathbf{H}_i are respectively the electric and magnetic fields, Z_0 the free space impedance, k the wave number and $u_i(x_i, z_i)$ the paraxial formulation of the GB.

Assuming $\beta_i < k$ the GB is centered on a propagative plane wave. Its direction of propagation forms an angle α_i with the z_i axis. This angle is given by

$$\alpha_i = \arcsin\left(\frac{\beta_i}{k}\right). \quad (4)$$

We associate with this beam a new coordinate system

$$\begin{aligned} x_i^\alpha &= x_i \cos(\alpha_i) - z_i \sin(\alpha_i), \\ z_i^\alpha &= x_i \sin(\alpha_i) + z_i \cos(\alpha_i). \end{aligned} \quad (5)$$

Via the steepest descent path method, we obtain the paraxial formulation of the beam

$$u_i(x_i, z_i) = a_{i0} \sqrt{\frac{q_{i0}^\alpha}{q_i^\alpha(z_i^\alpha)}} e^{-j \left(\frac{k x_i^{\alpha 2}}{2 q_i^\alpha(z_i^\alpha)} + \beta_i x_i^\alpha \right)} e^{-j k z_i^\alpha}, \quad (6)$$

with

$$\begin{aligned} q_{i0}^\alpha &= q_{i0} \cos^2(\alpha_i), \\ q_i^\alpha(z_i^\alpha) &= q_{i0}^\alpha + z_i^\alpha. \end{aligned} \quad (7)$$

2.4 Far-field formulation

In the far-field zone, the paraxial approximation leads to an important phase error that can induce errors when suming beams with different directions

of propagation. To overcome this problem, an alternative formulation exists that only depends on a far-field approximation. In spherical coordinates, this formulation is given by

$$\begin{aligned} \mathbf{E}_i(r, \theta) &= u_i(r, \theta) \cos(\theta) \hat{\mathbf{y}}_i, \\ \mathbf{H}_i(r, \theta) &= -\frac{u_i(r, \theta)}{Z_0} \left(\cos(\theta) \hat{\mathbf{x}}_i - \sin(\theta) \hat{\mathbf{z}}_i \right), \end{aligned} \quad (8)$$

with

$$u_i(r, \theta) = a_{i0} \sqrt{q_{i0}^\alpha} \cos(\theta) e^{j \frac{k}{2} \left(\sin(\theta) - \frac{\beta_i}{k} \right)^2 q_{i0}^\alpha} \frac{e^{-j k r}}{\sqrt{r}}. \quad (9)$$

3 Context and configuration

3.1 Configuration

We consider the configuration presented in Figure 1.

Figure 1: Configuration.

We suppose that the incident GB yields two beams. One transmitted and one reflected beam. Because the method is similar for both beams, only the study of the transmitted field will be presented in details.

3.2 Dichroic surface

The dichroic surface response, noted $\tilde{T}(k_x, z = 0)$ is assumed to be already known, for example in a tabulated form. In practice, this response can be computed numerically using a method based on Floquet modes (for example via HFSS or [4]).

4 Method

The configuration is presented in Figure 2. The transmitted GB must be as close as possible to the transmitted field. Therefore, the goal is to determine its reference frame and four parameters. Its reference frame is chosen to be the same as for the incident beam.

To determine the four parameters, we make a matching of the angular spectrum of the incident and transmitted beams through the dichroic surface. In order to keep spectrum with Gaussian

Figure 2: Configuration of the transmitted beam.

amplitudes, we choose to make this matching in the reference frame of the incident beam. In other words, the spectrum matching consists in writing

$$\tilde{u}_t(k_{xi}) = \tilde{T}(k_{xi})\tilde{u}_i(k_{xi}), \quad (10)$$

with $\tilde{u}_t(k_{xi})$, the spectrum of the transmitted field.

4.1 Calculation steps

4.1.1 Transmitted beam

In our method, there are three important steps. The first concerns the transmitted beam. We must express its angular spectrum in the reference frame of the incident GB. This spectrum is written as

$$\tilde{u}_t(k_{xi}) = a_{t0} \sqrt{-j \frac{2\pi}{k} q_{t0}} e^{j \frac{(k_{xi} - \beta_t)^2}{2k} q_{t0}} e^{jk_{xi} x_{t0}}. \quad (11)$$

4.1.2 Dichroic surface

The second step concerns the dichroic surface. As for the precedent step, we must express its response in the reference frame of the incident GB. Neglecting evanescent waves, this amounts to

$$k_{xi} = k_x \cos(\theta_i) - \sqrt{k^2 - k_x^2} \sin(\theta_i). \quad (12)$$

The identification requires the following approximation of the transmission coefficient

$$\tilde{T}(k_{xi}) \approx e^{T_0 + T_1 k_{xi} + T_2 k_{xi}^2}, \quad (13)$$

where T_0 , T_1 and T_2 can be complex. This approximation is obtained by means of a point matching technique on three points. One at the maximum of the incident beam and two at half of the maximum value.

4.1.3 Identification

The final step is the identification. From (2), (11) and (13) in (10), we obtain

$$\begin{aligned} q_{t0} &= q_{i0} - j2kT_2, \\ \beta_t &= \frac{\text{Im}(q_{i0})}{\text{Im}(q_{t0})} \beta_i + \frac{k}{\text{Im}(q_{t0})} \text{Re}(T_1), \\ x_{t0} &= \frac{1}{k} \left(\text{Re}(q_{t0}) \beta_t - \text{Re}(q_{i0}) \beta_i \right) + \text{Im}(T_1) + x_{i0}, \\ a_{t0} &= a_{i0} \sqrt{\frac{q_{i0}}{q_{t0}}} e^{T_0 + j \frac{1}{2k} (q_{i0} \beta_i^2 - q_{t0} \beta_t^2)}. \end{aligned} \quad (14)$$

Now we have all the parameters, we can use the equation (3) or (8) to compute the transmitted field.

4.2 Simplified formulation

When the response of the dichroic surface is slowly varying over k_{xi} , we can simplify the identification. Indeed, in this case T_1 and T_2 are equal to zero, which yields $q_{t0} = q_{i0}$, $\beta_t = \beta_i$ and $x_{t0} = x_{i0}$. This means that the transmitted GB is identical to the incident beam up to a coefficient. This coefficient is given by the response of the dichroic surface for $k_{xi} = 0$.

5 Simulation results

5.1 Dichroic surface without dielectric

The first computed dichroic surface is infinitely plane and placed at $z = 0$. The size of the period is $\lambda/2$ with a perfectly conducting metallization of 0.1λ . The incident GB has a waist size of λ positioned at $z_i = 0$. Furthermore, $\beta_i = 0$ and $\theta_i = 45^\circ$. The frequency is of 200GHz. The total near field is shown in Figure 3, on the left. The near field is compared to the one obtained with the reference method [4] on the right.

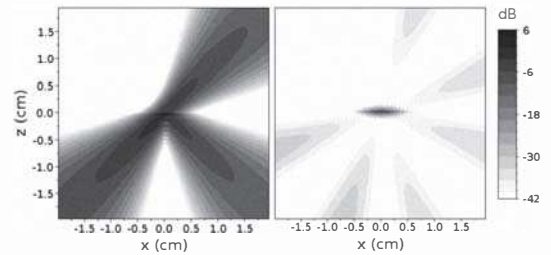

Figure 3: Total electric field (dB) with the spectrum matching (left), difference with MoM (right).

We can see in Figure 3 that our method gives very accurate results, with a difference below -40

dB. The only differences are due to neglecting the evanescent waves and assuming paraxiality of the incident beam. Indeed, we can see on the three GBs a residual error due to the near-field formulation, which is limited by the field paraxiality.

Figure 4: Normalized transmitted electric far-field (dB) : MoM (\triangleright), spectrum matching (\square) and simplified formulation (\diamond).

In Figure 4 we can see the far-field zone. The results are also very close to the reference method. This simulation leads to $\delta_t \approx 0.6^\circ$ and $x_t \approx 0.04\lambda$. Note that to compute one hundred points, MoM needs 29.42 s, spectrum matching only 33 ms. We can see in Figure 4 that the field computed with the simplified formulation is less accurate but remain close to the reference solution.

5.2 Dichroic surface on a dielectric

This second dichroic surface is composed of elements of period $\lambda/2$ with a perfectly conducting metallization of 0.1λ . It is laid on a dielectric having a thickness of $\lambda/8$ and a relative permittivity of 2.1. We choose for the incident beam $W_{i0} = 2\lambda$ and $z_{W_{i0}} \approx 1.3\lambda$. To test the method with a more demanding case, we take $\theta_i = 70^\circ$. The frequency is the same as previously. The far-field is shown in Fig. 5.

Figure 5: Normalized transmitted (left) and reflected (right) electric far-field : MoM (\triangleright), spectrum matching (\square) and simplified formulation (\diamond).

We observe in Figure 5 that the field is modified by the presence of the dichroic surface and applying a simple factor to the transmitted/reflected fields is not sufficient. We find $\beta_t \approx 0.024k$ ($\delta_t \approx 1.3^\circ$) and $x_{t0} \approx 0.7\lambda$ for the transmitted field and $\beta_r \approx 0.04k$ ($\delta_r \approx 2.3^\circ$) and $x_{r0} \approx 0.2\lambda$ for the reflected field. Moreover, the complex curvature radii of the two FGs are significantly modified. In this case, the simplified formulation leads to an important error.

5.3 Conclusion

In this paper, we have analyzed the interaction of a GB with a dichroic surface. We have proposed a new method for approaching the transmitted and reflected fields by two GBs. This allows to obtain an analytical formulation of the field.

We have successfully tested this technique in two test cases. We have also noticed that in case where the dichroic surface only slightly modifies the incident field, transmitted and reflected GBs are identical to the incident beam up to a coefficient.

For future works, we intend to extend this theory to 3D.
