HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Abstract
In this paper we review the activities of Air Traffic Control and Management (ATC/M) and expose scenarios that illustrate current and future challenges in this domain. In particular we look at those challenges that can be tackled with the use of immersion. We introduce the concepts of an immersive Remote Tower and Collaborative Immersive Trajectory analysis. These make use of immersive technologies such as Head Mounted Displays (HMDs) or large, tiled displays to immerse users in their tasks, better supporting the management and analysis of the complex data produced in this domain.

Introduction and Background
Air Traffic Control and Management (ATC and ATM) are activities involving the management of critical data at different times. In ATC, Air Traffic Controllers (ATCos) have to analyze copious information in real-time to
maintain traffic identity and security. In ATM, expert analysts analyse online large amounts of recorded data, such as aircraft trajectories, in order to understand past situations and improve future procedures. ATC is a multi-modal computer-supported cooperative work (CSCW) activity that involves "live" aircraft data visualisations along with many unstructured and complex data sources like audio communications. The main purpose of ATC is to maintain a safe distance between aircraft. With a predicted continual increase [3], air traffic is becoming more and more dense and complex to manage in real-time and also to analyse online to improve its security and identity.

Therefore, research and development in this domain remains very active and seeks to provide new solutions to improve security in this context. The focus of this paper is to present a set of innovative Immersive solutions for ATC/M that aims to support the ATCos and managers work in this increasingly complex environment. In this context, we introduce the concept of an Immersive Tower that aims to provide new real-time support and Collaborative Immersive trajectory analysis. This, in turn, aims to provide new ways to enhance remote aircraft trajectory analysis.

There is previous work investigating ATM and ATC from different perspectives, including tangible interaction, augmented reality and data visualisation.

Augmented Paper Strip

Air Traffic Controllers (ATCo) monitor traffic through real-time radar screens and communicate to pilots with radio systems. In addition, controllers use paper strips: one strip per aircraft with its planned flight route and additional information. Controllers can annotate, grasp, move, and organize these paper strips on a stripboard, using these tangible interactions to organize their mental picture [11]. Unfortunately, paper strips do not bridge the gap between the physical and digital worlds. Once printed, the paper strip cannot be updated, nor can the information reported on the strip be used as input into the system. This strong limitation hinders the development of more advanced ATC systems. For example, ideally more accurate future aircraft locations, complex conflict detections and resolutions all need to be available in real-time. Taking this limitation into account, the Strip'TIC (Strepping Tangible Interface for Controllers) system has been developed. This prototype combines augmented paper and digital pens on a multitouch glass stripboard, using vision-based tracking and augmented rear and front projections [8]. In this system, the user can manipulate the paper strips as tangible objects and use gestures to fulfill air traffic management [13]. Strip'TIC is the first attempt to support ATC activity with an immersive environment augmented with tangible objects (paper strips) and multimodalities (pen, touch, tangible objects). The work presented in this paper is a direct extension of this Strip'TIC prototype.

Air Traffic Data Analysis

Air Traffic Analysis can be performed with many different tools to extract knowledge from real-time or recorded information (i.e., aircraft trajectories). All of these tools can help to better understand traffic structure and evolution thanks to different metrics and interaction techniques [5]. Traffic can be analyzed from a flow perspective; the users can better compare recorded trajectories and dig into their temporal evolution [14]. Flow can also be visually explored thanks to simplification techniques like Edge Bundling [7]. The dynamics of such flows can be analyzed with dynamic network [6] and schematization techniques [9]. Flow dynamics can also be extracted with visual analytics tools [1]. Finally, this work...
analysis can provide unexpected information like meteorological parameters (i.e. wind direction) [4]. Few interaction techniques exist to manipulate a large quantity of aircraft trajectories. Fromdady shows the rst instance of such a paradigm [10].

Remote Tower and immersive environment
To maintain and improve safety and efficiency in ATC, the service providers need to constantly innovate with new systems and devices. The Remote Tower (RT) concept belongs to one of the most recent innovations [12]. The RT (Figure 1) fulfills ATC services from a location remote from the original control tower. A mast is deployed on the airfield with various sensors (cameras, radio antenna, etc.) and a video stream with additional information is transmitted to a remote site thanks to network communication systems. Many countries have started developing RTs to lower the building costs compared to actual tower and to provide ATC services in low-traffic or difficult to-access aerodromes. In order to better understand the RT challenges, we summarize in the following the design requirements of this concept:

Lowering costs: the RT project aims primarily to reduce operating costs and maintenance of small airfields. When the traffic density of an airfield is low, it is not profitable to maintain a control tower and its associated infrastructure.

Increasing the exibility of air navigation service. The opening hours of an airfield and the remote tower system operating mode could be adapted to the traffic density.

Restoring service in aerodromes with difficult access. Using a remote tower system, the technology is able to re-establish air navigation service in areas that are difficult to access or have unfavorable climate.

An alternate solution for large airports: in airports where the traffic density is high, it can be bene cial to have an additional control position. This also maintains continuity of service should any problems occur. Further, a relatively high tra c-management capacity can be maintained.

Increasing capacity: air traffic is expected to double in the next twenty years [3]. It is therefore essential for airports with high traffic density to increase their capacity. Furthermore, RT will provide a suitable solution when the traffic capacity has to be reduced due to low visibility conditions.

Usage Scenarios
Taking into account the RT design requirements, we identi ed many scenarios where immersive environments may improve ATC activity. These scenarios were designed during one brainstorming session with two HCI researchers, one research engineer and two expert ATCos.

Scenario: low visibility It is 9pm and there is heavy fog at the airport. Traffic density is high, which creates additional pressure on the ATCo. The ATCo cannot see either end of the runway and is controlling traffic following low-visibility rules. Since the ATCo cannot directly see the traffic, it is essential to use stop bars (mandatory stop locations close to the runway) to prevent undesirable actions. One aircraft is on nal approach and another aircraft is waiting on a holding point for the departure. The ATCo has given the incoming aircraft a landing authorization and is waiting for the pilot to report when it has vacated the runway. After receiving the report, the ATCo gives the line-up authorization (i.e. clearance) for the holding aircraft and turns off the stop bar lights. Due to the low visibility rules, this common situation takes much longer time than normally, so the capacity the airport decreases markedly. One solution is to
use thermal/infrared vision with virtual labels. Due to the low visibility, the ATCo turns on thermal vision to enhance the monitoring. This enables the controller to view the aircraft that is waiting at the holding point and the aircraft on nal approach. The ATCo can additionally see the information displayed in the virtual labels that are linked to the aircraft. When the aircraft has landed and the ATCo confirms by the position of the labels that the landing was successful and it has passed the waiting aircraft, clearance for the waiting aircraft to line up on the runway is given. As the aircraft starts moving, the ATCo receives feedback of the action on the label. The thermal/infrared vision allows the controller to see when the runway is vacated and can give take-off clearance with no delay. Having thermal/infrared vision and virtual labels in a control tower can increase the ATCo’s situational awareness, especially in low visibility. It is also bene cial for safety and e ciency concerns. However, if there are several aircraft near each other, the amount of labels could confuse the controller and cause dangerous situations.

Scenario: Sound location

It is 2pm. There are several small (e.g. VFR, Visual Flight Rules) and large (e.g. IFR, Instrument Flight Rules) aircraft in the airspace. A new aircraft enters the airspace and contacts the tower. The ATCo now knows the approximate position of the aircraft, but is unable to obtain visual contact because there are other aircraft in the same direction. A candidate solution is to use a sound location system. The RT has a surround system which reproduces any sound from an airport at its actual location. For example, if an aircraft that is contacting the tower is situated to the left of the controller, its emitting sound will come from the left. The system also indicates the distance from the airport by modulating the speech of the pilots that are further away. This allows the ATCo to distinguish the location of the aircraft and to obtain visual contact. The surround system gives the ATCos additional information about the aircraft’s position, which in turn can increase working speed. Spotting an aircraft from a tower can be di cult, even in good weather, but the help of the sound system may allow aircraft to be identi ed faster.

Immersive environment Implementation for ATC

The previous scenarios give a suitable overview of potential usage of immersive environment for ATC. In this section, we detail the implementation of our working prototype (Figure 3). In this prototype, the user wears an Oculus Rift HMD and is immersed in a 360-degree visual environment of a selected air eld. The user changes point of view on the eld with a vertical mid-air gesture. An horizontal mid-air gesture changes the visualisation to an infrared light source view (for low visibility cases). When the user gazes at an aircraft, the system displays the corresponding information (e.g. aircraft name, company). The 360 views use 8 images mapped on a sky box. Hand gestures are tracked with a Leapmotion, and we used the Unity game engine to integrate the HMD and 3D immersion.

Naturally, due to the prototypical nature of our current RT implementation, e cient interactions and visualisation techniques need to be explored and tested. However, this RT prototype helps us to better grasp how new interactions can leverage user activity in a Remote Tower. Several Air Tra c Controllers experimented this environment with simulated tra c, and they all agree that this prototype is an interesting proof of concept. This

Immersion & Collaborative Trajectories Visualization

The previous scenario illustrates the need for collaborative and immersive aircraft trajectories visualisation to support common understanding, share expertise and report situations from distant sites. Typically, this scenario is supported with 2D visualisation tools to show 3D aircraft trajectories, combined with video conferencing systems to share insights from distant sites. This communication support is not optimal for viewers when presenters navigate in the visualisation (e.g., when they perform pan and zoom operations), and describe and point at 3D data with 2D visualisations. We strongly hypothesise that the use of immersive technologies similar to the ones used in the Remote Tower (HMDs, hand tracking devices) will improve collaboration by enhancing spatial cognition and situational awareness by providing spatial affordances to analyse copious 3D trajectories.

For that purpose, we developed a prototype for collaborative aircraft trajectory visualisation that allows multiple users to analyse together a large quantity of aircraft trajectories using HMDs and hand tracking devices. As a collaborative platform for immersive big data visualisation, we identified the following design requirements:
RQ1 Immersive visualisation Users are visually immersed in the trajectory visualisations (stereo vision, head-tracking, change of point of view and position).

RQ2 Position indication and interactive rendez-vous The system indicates users' positions, and users can invite each other to share point of view.

RQ3 Pointing and Gaze The system supports users' pointing and gaze sharing to augment the sense of presence.

RQ4 Filtering The users can filter trajectories of interest (e.g. time filtering).

RQ5 Collaboration Users can connect from different geographical sites.

To address these requirements, we created a networked Unity application that enables a connection between two users from remote sites (RQ5, Figure 5, top). Each user on each site uses an Oculus Rift that delivers an immersive visualisation experience with stereo vision and head-tracking (RQ1, Figure 5, top). The hands and fingers of the users are tracked with a Leap Motion device (RQ3), and users view a high-fidelity feedback of the movement and position of their own hands in the Oculus Rift (Figure 5 (1)). Users can change their viewpoint by leaning and rotating their heads with the help of the head-tracking of the Oculus Rift. Users can navigate in the visualisation using a combination of gaze direction and the use of a game pad (RQ2). We developed a rendezvous interaction that allows each user to send their location in the virtual environment. The distant user receives a notification: an incoming message in their field of view. We developed basic filtering operations such that users can replay the traffic with the game pad (time filtering) and change the opacity of the trajectories (visual filtering to reduce clutter) (RQ4). The head and hand positions and rotations of each user are sent over the network using socket communication. Oral communication is supported with VOIP clients such as Skype or Zoom.

This platform is a rst prototype that aims to improve communication between remotely located ATC experts. With this novel and visually immersive prototype, the groups of experts from the previous stack formation scenario can connect with experts in Reims and run a collaborative visualisation session (Figure 5, top). The users start with an overview of the traffic (Figure 5 (1)). The expert in Reims navigates to the stack and sends a virtual rendezvous to share the relevant point of view to the distant user. Once the two users are at the same position in the virtual environment, the expert explains the formation of the stack with the use of his hands in the 3D environment. The expert explains how the planes were managed in this stack and how they were sequenced for landing in Paris and Brussels (Figure 5 (2), the green stack of aircraft trajectories). During the session, the two users are immersed in the three dimensional traffic trajectories and benefit from the affordances that the system offers. They can directly point at 3D trajectories with their hands and analyze the data collaboratively (Figure 5 (3)).

Conclusion And Future work

In this paper we exposed real-time and online ATC/M scenarios and how those activities can be supported with the use of different immersive solutions. In particular, we showed two immersive ATC/M prototypes for control and data data analysis. We introduced the Remote Tower, where the user can grasp the potential of an immersive environment to fulfill ATC tasks. This technique is promising but work remains to develop new interactions and visualisation techniques and to validate them. We also presented an early collaborative and immersive
prototype tool which enables experts to collaborate from
distant sites with the use of HMDs and hand tracking
devices. We believe that this type of platform will reduce
users’ cognitive e orts when collaboratively analyzing
trajectories, and improve their work ow and
comprehension of tra c (a recent study showed the bene
ts of collaboration with head mounted displays [2]).
However, further work is needed to re ne the design,
evaluate and validate this platform with expert users.
